FUNCTION DESCRIPTION

1 CPU Core

1.1 Program ROM (PROM)

The ROM of this device has an extra 32-Word INFO area to store the SYSCFG. The ROM can be written multi-times and can be read as long as the PROTECT (CFGWH.15) bit of SYSCFG is not set. The SYSCFG can be read no matter PROTECT is set or cleared, but PROTECT bit can be cleared only when User ROM Code area is erased. On the other hand, if PROTECT bit is set, the user ROM code area will not be read by writer, and the user ROM code can't be updated until the PROTECT bit is cleared. The endurance of ROM is 1000 times @V_{cc}=5V/25°C °.

Change this register at slow clock for safety.

The user must switch this register to “8ns” to enhance the performance of minimal operating voltage.

This feature can't be emulated.

1.1.1 Reset Vector (000h)

After reset, system will restart the program counter (PC) at the address 000h, all registers will revert to the default value.

1.1.2 Interrupt Vector (004h)

When an interrupt occurs, the program counter (PC) will be pushed onto the stack and jumps to address 004h.

1.2 System Configuration Register (SYSCFG)

The System Configuration Register (SYSCFG) is located at INFO area; it contains a 16 bits register (CFGWH). The SYSCFG determines the option for initial condition of CPU. It is written by PROM Write only. User can select LVR operation mode and chip operation mode by SYSCFG register. The 15th bit of CFGWH is code-protected selection bit. If this bit is 1, the data in PROM will be protected when user reads PROM.

1.3 RAM Addressing Mode

There is one Data Memory Plane in CPU. The Plane is partitioned into four banks. Each bank extends up to 7Fh (128 bytes). The lower locations of each bank are reserved for Special Function Register (SFR). Above the SFR are General Purpose Registers, implemented as static RAM. All implemented banks contain Special Function Registers. Some frequently used Special Function Registers from one bank may be mirrored in another bank for code reduction and quicker access.

Bit RP1 and RP0 (STATUS[6:5]) are the bank select bits.

[RP1, RP0]	BANK
00	0
01	1
10	2
11	3

The plane can be addressed directly or indirectly. The INDF register is not a physical register. Addressing the INDF register will cause indirect addressing. Indirect addressing is possible by using the

INDF register. Any instruction using the INDF register actually accesses the register pointed to by File Select Register, FSR. Reading the INDF register itself, indirectly (FSR = '0') will read 00h. Writing to the INDF register indirectly (FSR = '0') results in a no operation (although status bit may be affected). An effective 9-bit address is obtained by concatenating the 8-bit FSR register and the IRP bit (STATUS[7]). Refer to the figure below.

Direct / Indirect Addressing

Keeping RP0=RP1=0 in the beginning of the F/W code and using the new instruction set.

The advantage of using new instruction is user can ignore the bank location of registers and the code size can be saved. The new instruction is almost the same as the old instruction. By replacing the “F” to “X” in the instruction set can easily use the new instruction without switching the bank.

For example:

1.4 Programming Counter (PC) and Stack

The Programming Counter is 12-bit wide. As a program instruction is executed, the PC will contain the address of the next program instruction to be executed. The PC value is normally increased by one except for the following cases. The Reset Vector (000h) and the Interrupt Vector (004h) are provided for PC initialization and Interrupt. For CALL/GOTO instruction, PC loads lower 11 bits address from instruction word and upper 1 bit from PCLATH[3]. For RET/RETI/RETLW instruction, PC retrieves its content from the top level STACK.

Before CALL/GOTO instruction is executed, the PCLATH[3] must be set if the destination address more than 2K, otherwise the PCLATH[3] must be cleared. Similar as RAM Addressing Mode (refer section 1.3), the Chip provides new instruction set LCALL/LGOTO to replace CALL/GOTO instruction set. When using LCALL/LGOTO, user don't care about the destination address, just only keep PCLATH[3] cleared.

The low byte data of the Programming Counter (PC[7:0]) can be read and written by PCL register (002h/082h/102h/182h). The high byte data of Programming Counter (PC[11:8]) can only be read by PCH register (10Ch). The internal flag PCH_S is used to select the source of PCH, when executing any instruction with the PCL register as the destination. Write 0x1C to PCH register can set PCH_S, write others value to PCH register will clear PCH_S. After reset, the PCH_S is cleared.

When PCH_S is cleared to '0', executing any instruction with the PCL register as the destination simultaneously causes PCH to be replaced by the contents of the PCLATH (00Ah/08Ah/10Ah/18Ah) register. This allows the entire contents of the program counter to be changed by writing the desired high byte to the PCLATH register. When the low byte is written to the PCL register, all contents of program counter will change to the values contained in the PCLATH register and those being written to the PCL register.

When PCH_S is set to '1', executing any instruction with the PCL register as the destination the low byte is written to the PCL register and will not change the PCH. It is recommended to setting PCH_S to '1' when using any instruction with the PCL register as the destination, but C language doesn't support this function.

The STACK is 12-bit wide and 8-level in depth. The LCALL instruction and hardware interrupt will push STACK level in order, while the RET/RETI/RETLW instruction pops STACK level in order. For table lookup, the device offer the powerful table read instructions TABRL, TABRH to return the 16-bit ROM data into W and TABR register by setting DPTR={DPH, DPL} registers. It also offers another way to read the 16-bit ROM data into W and TABR register by setting TABR (18Ch) for C language.

◇ Example: To look up the PROM data located “TABLE1” and “TABLE2”.

Note: The chip define 256 ROM address as one page, so that ROM has 16 pages, 000h~0FFh, 100h~1FFh, ..., F00h~FFFh. On the other words, PC[11:8] can be define as page. A lookup table must be located at the same page to avoid getting wrong data. Thus, the lookup table has maximum 255 data for above example with starting a lookup table at X00h (X = 1, 2, 3, ..., E, F). If a lookup table has fewer data, it needs not setting the starting address at X00h, but only confirms all lookup table data are located at the same page.

- Table Read for C: using register TABR. Only be used outside or inside the interrupt service routine. Don't utilize it inside and outside interrupt service routine simultaneously. Otherwise, something will be wrong.*

1.4.1 ALU and Working (W) Register

The ALU is 8-bit wide and capable of addition, subtraction, shift and logical operations. In two-operand instructions, typically one operand is the W register, which is an 8-bit non-addressable register used for ALU operations. The other operand is either a file register or an immediate constant. In single operand instructions, the operand is either W register or a file register. Depending on the instruction executed, the ALU may affect the values of Carry (C), Digit Carry (DC), and Zero (Z) Flags in the STATUS register. The C and DC flags operate as a /Borrow and /Digit Borrow, respectively, in subtraction.

Note: /Borrow represents inverted of Borrow register.

/Digit Borrow represents inverted of Digit Borrow register.

1.4.2 STATUS Register (003h/083h/103h/183h)

This register contains the arithmetic status of ALU and the Reset status. The STATUS register can be the destination for any instruction, as with any other register. If the STATUS register is the destination for an instruction that affects the Z, DC or C bits, then the write to these three bits is disabled. These bits are set or cleared according to the device logic. It is recommended, therefore, that only BCX, BSX and MOVWX instructions are used to alter the STATUS Register because these instructions do not affect those bits.

```

2 Reset

This device can be RESET in four ways.

- Power-On-Reset (POR)
- Low Voltage Reset (LVR)
- External Pin Reset (XRST)
- Watchdog Timer Reset (WDTR)

Resets can be caused by Power on Reset (POR), External Pin Reset (XRST), Watchdog Timer Reset (WDTR), or Low Voltage Reset (LVR). The CFGWH controls the Reset functionality. After Reset, the SFRs are returned to their default value, the program counter (PC) is cleared, and the system starts running from the reset vector 000h place. The TO and PD flags at status register (STATUS) are indicate system reset status.

2.1 Power on Reset (POR)

After Power-On-Reset, all system and peripheral control registers are then set to their default hardware Reset values.

2.2 Low Voltage Reset (LVR)

The Low Voltage Reset features static reset when supply voltage is below a threshold level. There are 16 threshold levels can be selected. The LVR's operation mode is defined by the CFGWH register. Please refer to the table of LVR voltage in the chapter of Electrical Characteristics. Vcc must be below maximum operating voltage and above LVR voltage. The user must consider the minimal operating voltage of corresponding operating frequency such that LVR voltage must be above minimum operating voltage.

Different F_{sys} have different system minimum operating voltage, reference to Operating Voltage of DC characteristics, if current system voltage is low than minimum operating voltage and lower LVR is selected, then the system maybe enters dead-band and error occurs.

16h	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
LVCTL	LVDF	LVDHYS	LVRSAV	LVDSAV	LVDS			
R/W	R	R/W	R/W	R/W	R/W			
Reset	0	0	1	1	0	0	0	0

- 16h.5 **LVRSAV:** POR/LVR auto power off in STOP/IDLE mode
 0: disable POR/LVR auto power off in STOP/IDLE mode
 1: enable POR/LVR auto power off in STOP/IDLE mode

2.3 External Pin Reset (XRST)

The External Pin Reset (XRST) can be disabled or enabled by XRSTE at CFGWH register. External pin reset should be kept low for at least 2 SIRC clock cycles to ensure reset can active. The External Pin Reset also sets all the control registers to their default value but the TO/PD flags will not affected by these resets.

External reset pin (nRESET) is low level active. The system is running when reset pin is high level voltage input. The reset pin receives the low voltage and the system is reset. The external reset can reset the system during power on duration, and good external reset circuit can protect the system to avoid operating at inappropriate power condition.

2.4 Watchdog Timer Reset (WDTR)

The WDT reset can be disabled or enabled through the CFGWH register. Set WDTOSC to define the period during which WDT reset occurs. WDT reset counter can be cleared by device Reset or CLRWDT bit. WDT reset also set all the control registers to their default value. The TO/PD flags are not affected by WDT resets.

◇ Example: Defining Reset Vector

```

ORG      000h                ; Reset Vector
LGOTO    START                ; Jump to user program address.

ORG      010h

...                ; 010h, The head of user program
...
LGOTO    START

3 Clock Circuitry and Operation Mode

3.1 System Clock

The device is designed with dual-clock system. There are four kinds of clock source, FXT (Fast Crystal) Clock, SXT (Slow Crystal) Clock, SIRC (Slow Internal RC) Clock and FIRC (Fast Internal RC) Clock. Each clock source can be applied to CPU kernel as system clock. When in IDLE mode, the Slow-clock (SIRC or SXT) can be configured to keep oscillating to provide clock source to T2 block, or the SIRC provides clock source to WKT/WDT block. Refer to the Figure as below.

After Reset, the device is running at SLOW mode with SIRC. S/W should select the proper clock rate for chip operation safety. The higher V_{CC} allows the chip to run at a higher System clock frequency. In a typical condition, a 16 MHz System clock rate requires $V_{CC} > 2V @ (25^{\circ}C)$.

The CLKCTL (0Fh) SFR controls the System clock operating. H/W automatically blocks the S/W abnormally setting for this register. Never to write both FASTSTP=1 and CPUCKS=1. It is recommended to write this SFR bit by bit.

Clock Scheme Block Diagram

The frequency of FIRC can be adjusted by IRCF (10Fh). When IRCF=00h, frequency is the lowest. When IRCF=7Fh, frequency is the highest. With this function, we can adjust the frequency of FIRC after power on. Each IC may have different default value of IRCF, to make sure the frequency of FIRC=16 MHz after Power on Reset.

FAST Mode:

In this mode, the program is executed using FIRC or FXT as CPU clock (Fsys). The Timer0, Timer1 blocks are also driven by Fast-clock. The PWM0 block can be driven by Fsys, FIRC (16 MHz), or FIRC*2 (32 MHz) by setting PWMCKS (91h.5~4). T2 can be driven by Slow-clock, Fsys/128, or FIRC/512 (16 MHz/512) by setting T2CKS (15h.3~2).

SLOW Mode:

After power-on or reset, device enters SLOW mode, the default Slow-clock is SIRC. In this mode, the Fast-clock can stopped (by FASTSTP=1, for power saving) or running (by FASTSTP=0), and Slow-clock is enabled. All peripheral blocks (Timer0, Timer1, etc...) clock source are Slow-clock in the SLOW mode, except PWM and T2 blocks, which can select other clock source. There are two kinds of SLOW clock can be selected, SIRC and SXT.

IDLE Mode:

After executing the SLEEP instruction, if SIRC or SXT is still oscillating, it means entering IDLE mode. IDLE mode is terminated by Reset or enabled Interrupts wake-up. There are two ways to keep SIRC or SXT oscillating in IDLE mode.

- (1) Set SLOWSTP=0, before executing the SLEEP instruction, the SIRC or SXT can still oscillate. In this situation, Slow-clock can continue to oscillate to provide T2 block running in IDLE mode.
- (2) Set WKTIE=1 or WDTE=11, before executing the SLEEP instruction, the SIRC can still oscillate to keep WKT/WDT operating in IDLE mode.

STOP Mode:

When SLOWSTP (0Fh.4) is set, WKTIE (0Bh.3) is cleared and WDTE=0x or 10, all blocks will be turned off and the chip will enter the “STOP Mode” after executing the SLEEP instruction. STOP mode is similar to IDLE mode. The difference is all clock oscillators either Fast-clock or Slow-clock are stopped and no clocks are generated.

3.2 Dual System Clock Modes Transition

The device is operated in one of four modes: FAST mode, SLOW mode, IDLE mode, and STOP mode.

CPU Mode & Clock Functions Table:

IDLE	Stop	Stop	Run	Stop	Set by T2CKS	Set by WKTIE	Set by WDT	WKT/IO/T2
STOP	Stop	Stop	Stop	Stop	Stop	Stop	Stop	IO

● FAST mode switches to SLOW mode

The following steps are suggested to be executed by order when FAST mode switches to SLOW mode:

- (1) Switch to Slow-clock (CPUCKS=0)
- (2) Stop Fast-clock (FASTSTP=1)

◇ Example: Switch FAST mode to SLOW mode.

BCX	CPUCKS	; Fsys=Slow-clock
BSX	FASTSTP	; Disable Fast-clock

● SLOW mode switches to FAST mode

SLOW mode can be enabled by CPUCKS=0 in CLKCTL register. The following steps are suggested to be executed by order when SLOW mode switches to FAST mode:

- (1) Enable Fast-clock (FASTSTP=0)
- (2) Switch to Fast-clock (CPUCKS=1)

◇ Example: Switch SLOW mode to FAST mode (The Fast-clock stop).

BCX	FASTSTP	; Enable Fast-clock
NOP		
BSX	CPUCKS	; Fsys=Fast-clock

● IDLE mode Setting

The IDLE mode can be configured by following setting in order:

- (1) Enable Slow-clock (SLOWSTP=0) or WKT (WKTIE=1) or WDT (WDTE=11b)
- (2) Switch T2 clock source to Slow-clock (T2CKS=0)
- (3) Execute SLEEP instruction

IDLE mode can be waked up by External interrupt, WKT interrupt and T2 interrupt.

◇ Example: Switch FAST/SLOW mode to IDLE mode.

BCX	SLOWSTP	; Enable Slow-clock after execute SLEEP instruction
MOVLW	0000 <u>00</u> 00b	
MOVWX	T2CTL	
SLEEP		; Enter IDLE mode

● STOP Mode Setting

The STOP mode can be configured by following setting in order:

- (1) Stop Slow-clock (SLOWSTP=1)
- (2) Stop WKT (WKTIE=0)
- (3) Execute SLEEP instruction

STOP mode can be woken up only by external pin interrupt.

Note: CPU will not enter STOP mode if WDTE=11b

◇ Example: Switch FAST/SLOW mode to STOP mode.

```

BSX          SLOWSTP          ; Disable Slow-clock after execute SLEEP instruction
MOVLW        00000000b        ; Disable WKT counting
MOVWX        INTIE
SLEEP        ; Enter STOP mode.

3.3 System Clock Oscillator

In the Fast Internal RC (FIRC) mode, the on-chip oscillator generates 16 MHz system clock. In Slow/Fast Crystal (SXT/FXT) mode, a crystal or ceramic resonator is connected to XI and XO pins to establish oscillation. Since power noise degrades the performance of Internal Clock Oscillator, placing power supply bypass capacitors 1 μ F and 0.1 μ F very close to VCC/VSS pins improves the stability of clock and the overall system.

4 Interrupt

The Chip has 1 level, 1 vector and 11 interrupt sources. Each interrupt source has its own enable control bit. An interrupt event will set its individual pending flag, no matter its enable control bit is 0 or 1.

If the corresponding interrupt enable bit (INTIE[7:0], INTIE1[4], INTIE1[1:0]) has been set, it would trigger CPU to service the interrupt. CPU accepts interrupt at the end of current executed instruction cycle. In the meanwhile, a “LCALL 004” instruction is inserted to CPU, and i-flag is set to prevent recursive interrupt nesting.

The i-flag is cleared in the instruction after the “RETI” instruction. That is, at least one instruction in main program is executed before service the pending interrupt. The interrupt event is level triggered. F/W must clear the interrupt event register while serving the interrupt routine.

◇ Example: Setup INT1 (PA1) interrupt request with rising edge trigger

Each IO has 4 bits as the mode setting. The mode setting can include the following functions: open drain output, CMOS output, pull-up resistor, pull-down resistor, pin-change wake-up, PWMO and so on. All IO except PA7 support two sink current options, which are defined by the HSINK (105h.2). **PA7 has no high-sink, 1/2 bias and resistor pull-down capability.**

These pins can be operated in different modes as below table.

6 Peripheral Functional Block

6.1 Watchdog (WDT) /Wake-up (WKT) Timer

The WDT and WKT share the same built-in internal RC Oscillator and have individual counters. The overflow period of WDT, WKT can be selected by individual prescaler (WDTPSC[1:0], WKTTPSC[1:0]). The WDT timer is cleared by the CLRWDT instruction. If the Watchdog is enabled, the WDT generates the chip reset signal.

The WKT timer is an interval timer, WKT time out will generate WKT Interrupt Flag (WKTIF). The WKT timer is cleared/stopped by WKTIE=0. Set WKTIE=1, the WKT timer will always count regardless at any CPU operating mode.

WDT/WKT Block Diagram

The WDT's behavior in different Mode is shown as below table.

Mode	CFGWH[13:12]		WDT
	WDTE[1]	WDTE[0]	
Normal Mode	0	0	Stop
	0	1	Stop
	1	0	Run
	1	1	Run
Power-down Mode (SLEEP)	0	0	Stop
	0	1	Stop
	1	0	Stop

Watchdog clear is controlled by CLRWDT instruction.

6.2 Timer0

Timer0(TM0) (01h.7~0) is an 8-bit wide register. It can be read or written as any other register. Besides, Timer0 increases itself periodically and automatically rolls over a new "offset value" (TM0RLD) while it rolls over based on the pre-scaled clock source, which can be $F_{sys}/2$ or TM0CKI (PA2) rising/falling input. The Timer0 increase rate is determined by "Timer0 Pre-Scale" (TM0PSC) register. The Timer0 always generates TM0IF (0Ch.4) when its count rolls over. It generates Timer0 Interrupt if TM0IE (0Bh.4) is set. Timer0 can be stopped counting if the TM0STP (11h.6) bit is set.

Timer0 Block Diagram

The following timing diagram describes the Timer0 works in pure Timer mode.

When the Timer0 prescaler (TM0PSC) is written, the internal 8-bit prescaler will be cleared to 0 to make the counting period correct at the first Timer0 count. TM0CLK is the internal signal that causes the Timer0 to increase by 1 at the end of TM0CLK. TM0WR is also the internal signal that indicates the Timer0 is directly written by instruction; meanwhile, the internal 8-bit prescaler will be cleared. When Timer0 counts from FFh to TM0RLD, TM0IF (Timer0 Interrupt Flag) will be set to 1, and generate interrupt if TM0IE (Timer0 Interrupt Enable) is set.

Timer0 works in Timer mode (TM0CKS=0)

The equation of Timer0 interrupt time value is as following:

$$\text{Timer0 interrupt frequency} = F_{\text{sys}} / 2 / \text{TM0PSC} / (256 - \text{TM0RLD})$$

◇ Example: Setup Timer0 work in Timer mode, if Fsys = 8 MHz

; Setup Timer0 clock source and divider

```
MOVLW    00x00101b    ; TM0CKS = 0, Timer0 clock is instruction cycle
MOVWX    TM0CTL        ; TM0PSC = 0101b, divided by 32
```

; Setup Timer0 reload data

```
MOVLW    80h
MOVWX    TM0RLD        ; Set Timer0 reload data = 128
```

; Setup Timer0

```
BSX      TM0STP        ; Timer0 stops counting
CLR      TM0           ; Clear Timer0 content
```

; Enable Timer0 and interrupt function

```
MOVLW    11101111b    ; Clear Timer0 request interrupt flag
MOVWX    INTIF
BSX      TM0IE         ; Enable Timer0 interrupt function
BCX      TM0STP        ; Enable Timer0 counting
```

Timer0 interrupt frequency = Fsys / 2 / TM0PSC / (256-TM0RLD),

Fsys = 8 MHz, TM0PSC = div 32, TM0RLD = 128

Timer0 interrupt frequency = 8 MHz / 2 / 32 / (256-128) = 0.976 KHz

The following timing diagram describes the Timer0 works in Counter mode.

If TM0CKS=1 then Timer0 counter source clock is from TM0CKI pin. TM0CKI signal is synchronized by instruction cycle ($F_{sys}/2$) that means the high/low time durations of TM0CKI must be longer than one instruction cycle time ($F_{sys}/2$) to guarantee each TM0CKI's change will be detected correctly by the synchronizer.

Timer0 works in Counter mode for TM0CKI (TM0EDG=0), TM0CKS=1

◇ Example: Setup TM0 work in Counter mode and clock source from TM0CKI pin (PA2)

```

; Setup Timer0 clock source and divider
    MOVLW    00110000B    ; TM0EDG = 1, counting edge is falling edge
    MOVWX    TM0CTL        ; TM0CKS = 1, Timer0 clock is TM0CKI
                                ; TM0PSC = 0000b, divided by 1

; Setup Timer0

6.3 Timer1

Timer1(TM1) (12h.7~0) is an 8-bit wide register. It can be read or written as any other register. Besides, Timer1 increases itself periodically and automatically reloads a new "offset value" (TM1RLD) while it rolls over based on the pre-scaled instruction clock ($F_{sys}/2$). The Timer1 increase rate is determined by TM1PSC register. It generates Timer1 interrupt if the TM1IE bit is set. Timer1 can be stopped counting if the TM1STP bit is set.

6.4 T2:15-bit Timer

The T2 is a 15-bit counter and the clock sources are from Slow-clock, Fsys/128, or FIRC/512 (16 MHz/512). It is used to generate time base interrupt and T2 counter block clock. The T2 content cannot be read by instructions. It generates interrupt flag T2IF (0Ch.6) with the clock divided by 32768/16384/8192/128 depends on T2PSC[1:0] (15h.1~0) register bits. The following figure shows the block diagram of T2.

There are six PWMs in this chip. PWM0~PWM5 have independent 16-bit duty control register, and share a set of 16-bit period register. The PWM can generate varies frequency waveform with 65536 duty resolution on the basis of the PWM clock. The PWM clock can select Fsys, FIRC (16 MHz), or FIRC*2 (32 MHz) as its clock source. The following takes PWM0 as an example for description.

If PWMEN is cleared, the PWM0~5 will be cleared and stopped, otherwise the PWM0~5 remain running. The PWM0 structure is shown as follow. The PWM0 duty cycle can be changed by writing to PWM0DH and PWM0DL. The PWM0 output signal resets to a low level whenever the 16-bit base counter matches the 16-bit PWM0 duty register {PWM0DH, PWM0DL}. The PWM0 period can be set by writing the period value to the PWMPRDH and PWMPRDL registers. After writing the PWM0DH or PWMPRDH register, H/W will update PWM period and duty immediately. PWM0~5 share an interrupt flag, and an interrupt flag is generated at the end of the period.

Only PWM0 has dead-zone(non-overlap) control, and is divided into PWM0P and PWM0N outputs, and the remaining PWM1~PWM5 have no dead-zone(non-overlap) control. The PWM1~5 outputs are PWM1O~PWM5O. User can use pin mode setting to output PWMxO to the corresponding IO pin, refer to Chapter 5 for more information on pin settings.

Only PWM0 can be output via PWM0P and PWM0N with four different modes. The edges of the PWM pulse can be separated with 16 different dead-zone(non-overlap) clocks intervals (T_{nov}). The width of T_{nov} can be selected by PWM0DZ (89h.3~0) within 0~15 PWM clock. The default output form is Mode0. The waveforms of the four output modes are shown below.

◇ Example:

; Setup Pin mode

```
MOVLW    xxxx0111b    ;
MOVWX    PAMOD54      ; PA4 Pin as PWM0P
```

```
MOVLW    xxxx0111b    ;
MOVWX    PAMOD76      ; PA6 Pin as PWM0N
```

; Setup PWM0 clock source select

```
MOVLW    xx10xxxxb    ;
MOVWX    OPTION2      ; FIRC 16 MHz as PWM clock source
```

; Setup PWM0 period and duty setting

```
MOVLW    FFh
MOVWX    PWMPRDL      ; write sequence: PWMPRDL then PWMPRDH
MOVLW    7Fh
MOVWX    PWMPRDH      ; Set PWM period = 7FFFh
```

```
MOVLW    00h
MOVWX    PWM0DL      ; write sequence: PWM0DL then PWM0DH
MOVLW    40h
MOVWX    PWM0DH      ; Set PWM0 duty = 4000h
```

; Setup PWM0 enable and dead-zone(non-overlap) control

```
MOVLW    10000000b    ; 89h.7 = 1, PWM0 enable
MOVWX    PWMCTL        ; 89h.5~4 = 0, PWM0 Mode0 output
                        ; 89h.3~0 = 0, PWM0 dead-zone(non-overlap) output
                        ; disable
```

Example:

PWM0 clock source = FIRC 16 MHz, PWM period = 7FFFh, PWM duty = 4000h

PWM0 output frequency = 16 MHz / (period+1) = 16 MHz / 32768 = 488 Hz.

PWM0 output duty = duty / (period+1) = 50 %.

6.6 Analog-to-Digital Converter

The 12-bit ADC (Analog to Digital Converter) consists of a 15-channel analog input multiplexer, control register, clock generator, 12-bit successive approximation register, and output data register. To use the ADC, user needs to set ADCKS (18h.2~0) to choose a proper ADC clock frequency, which must be less than 1 MHz. User then launches the ADC conversion by setting the ADST (18h.3) control bit. After end of conversion, H/W automatic clears the ADST (18h.3) bit. User can poll this bit to know the conversion status. When the IO pin is used as the ADC input pin, the corresponding pin mode should be set to 0011b. User needs to set ADCHS (19h.4~0) to choose the input channel of ADC. Besides, there are some reference input channel can be selected, ADC14 is VBG and ADC23 is 1/4VCC for ADC. ADC reference voltage can be configured as V_{CC} or V_{BG} by ADVREFS (19h.7~6). Furthermore, if ADVREFS is changed to 2.48V or 2V, it will need 200uS warm-up stable time. When ADCHS is selected to VBG, ADVREFS must be set to V_{CC} , otherwise ADC conversion will be invalid.

Example:

[CPU running at FAST mode , Fsys = FIRC 16 MHz]
ADC clock frequency = 1 MHz, ADC channel = ADC2 (PA2).

◇ Example:

```

MOVLW    xxxx0011b          ; ADC2 (PA2) as ADC input
MOVWX    PAMOD32

MOVLW    00000100b          ; ADCKS = Fsys/16, ADC clock = 1 MHz

MOVWX    ADCTL2              ; ADC input channel select ADC2

BSX      ADST                 ; 18h.3 (ADST), ADC start conversion.

```

WAIT_ADC:

```

BTXSC     ADST                 ; Wait ADC conversion finish.
LGOTO     WAIT_ADC

MOVXW     ADCDH                ; Read ADC output data bit 11~4

6.7 Comparator

There is a Comparator (CMP) in this device.

The CMP built in a 7-bit DAC module, which output can be accessed to negative input port of the CMP.

Reference Voltage of DAC can be selected as V_{CC} or V_{BG} by setting SVRF (18Fh.7). V_{BG} will be configured as 1.20V or 2.48V by setting ADVREFS (19h.7~6). A suitable level of voltage can be selected for proper operation of user application by setting SVL (18Fh.6~0), which will change the resistance to transform the value of voltage. Setting the PDCMP=1 (18Dh.7) will let DAC and CMP enter power down mode. By configuring SCMPN (18Eh.7), negative port input source will be external pin input or DAC output. And positive port input source is external pin input. The SCIN (18Eh.6~4) and SCIP (18Eh.2~0) register determine negative and positive port external input source respectively.

Because the input module of the CMP is composed of PMOS, the input voltage range will be affected by V_{th} of the PMOS. Thus, the maximum input voltage of the CMP will be $(V_{CC}-0.5) V$. Meanwhile, the Comparator's hysteresis voltage is about 30mV.

The Comparator original output (CMPOX) can be read by CMPOX (18Dh.6) bit. The Chip provides a de-bounce module to de-bounce the CMPOX signal, user can select de-bounce time by CMPDBS (18Dh.1~0). The de-bounce output signal can select invert or not by CMPINV (18Dh.4) to generate CMPO signal. The CMPO can be output to pin (PA5) by set CMPOE (18Dh.5) and the PA5MOD should be set to xx10b.

The CMPO is also a trigger source for the interrupt trigger module to generate interrupt flag CMPIF (0Eh.4). The trigger mode is selected by CMPTRIG (18Dh.3~2). When Comparator power down, the interrupt flag will still be produced. Therefore, it is necessary to clear the interrupt flag first after turning on the CMP module each time to prevent using the dummy flag.

6.8 Cyclic Redundancy Check (CRC)

The chip supports an integrated 16-bit Cyclic Redundancy Check function. The Cyclic Redundancy Check (CRC) calculation unit is an error detection technique test algorithm and uses to verify data transmission or storage data correctness. The CRC calculation takes an 8-bit data stream or a block of data as input and generates a 16-bit output remainder. The data stream is calculated by the same generator polynomial.

CRC16 Block Diagram

The CRC generator provides the 16-bit CRC result calculation based on the CRC-16-IBM polynomial. In this CRC generator, there is only one polynomial available for the numeric values calculation. It can't support the 16-bit CRC calculations based on any other polynomials. Each write operation to the CRCIN register creates a combination of the previous CRC value stored in the CRCDH and CRCDL registers. It will take one MCU instruction cycle to calculate.

6.9 S/W Control LCD Driver

The chip support an S/W controlled method to driving LCD. All IO pins except PA7 could be the Common Pins. Common pins are capable of driving 1/2 bias by setting the register PAxMOD/PBxMOD. The COM0 circuit is shown below.

LCD COM0 Circuit

The frequency of any repeating waveform output on the COM pin can be used to represent the LCD frame rate. The figure below shows an LCD frame.

INSTRUCTION SET

Each instruction is a 16-bit word divided into an Op Code, which specifies the instruction type, and one or more operands, which further specify the operation of the instruction. The instructions can be categorized as byte-oriented, bit-oriented and literal operations list in the following table.

For byte-oriented instructions, “f” represents the address designator and “d” represents the destination designator. The address designator is used to specify which address in Program memory is to be used by the instruction. The destination designator specifies where the result of the operation is to be placed. If “d” is “0”, the result is placed in the W register. If “d” is “1”, the result is placed in the address specified in the instruction.

For bit-oriented instructions, “b” represents a bit field designator, which selects the number of the bit affected by the operation, while “f” represents the address designator. For literal operations, “k” represents the literal or constant value.
